* Note that for synthetic reasons, the biotin modification was moved from the anchor strand to the hairpin strand between single and dual biotin experiments, respectively; we expect this effect to be negligible.

## - Spacers <br> + Spacers

Figure S1 Influence of spacer and overhang sequences on three-way junctions in tension probes.

NUPACK equilibrium pair probability analysis of DNA tension probes in the closed and open conformations. $50 \mu \mathrm{M}$ probes with $10 \%$ excess 'donor strand' were modeled at 25 C in 137 mM NaCl , corresponding to 1 xPBS and the approximate conditions for probe incubation on the SLB. The equilibrium pair probability is the probability of base-pairing.

Base-Pairs
1-3: Stable in all simulations a-d: Stable in some simulations

Figure S2 Molecular dynamics simulation results are independent of starting conformation
(A) Graphical schematic of modeled DNA hairpins. Probes were modeled with or without 3T spacers and a 5T overhang. For each hairpin, the distance between the bases was calculated at the sites shown in red, which are labeled a-d or 1-3. BP 1-3 were stable throughout all simulations, whereas BP a-d exhibited fraying in some simulations and conformations. Stable base-pairing is defined as two bases with less than or equal to $2 \AA$. (B) Histogram analysis of distance versus frequency for the indicated DNA bp. BP a-d correspond to the labeled bp in A. Individual histogram events quantify distances at simulation snapshots. Traces are coded by simulation, with the first simulation in red, the second in green, and the third in blue. (C) Histogram analysis of distance versus frequency for the indicated DNA bp. BP 1-3 correspond to the labeled bp in $\mathbf{A}$. Individual histogram events quantify distances at simulation snapshots. Traces are coded by simulation, with the first simulation in red, the second in green, and the third in blue.

Figure S6 Absorbance spectra of single-dye modified tension probes.

Schematics and absorption spectra of tension probes labeled only with the donor (A) or acceptor (B). Spectra represent the mean $\pm$ s.e.m. for 3 experiments. Outlier spectra (baseline $\pm 3$ median absolute deviations) were omitted.

Figure S7 Computed absorbance spectra for tension probes.

#### Abstract

Absorbance spectra for (A) Cy3B/BHQ1 (B) A488/Cy3B and (C) A488/BHQ1 probes were calculated by adding absorbance spectra of donor or acceptor only probes (Figure S6) normalized by fractional extinction coefficient. Data represent the mean $\pm$ s.e.m. and depict the expected signal for pure FRET or DET probes.

Figure S8 Representative TCSPC decay curves and fits

Representative TCSPC decay curves and curve fits (dashed black lines) and residuals for closed and open tension probes on SLBs. Probes were fit in SymPhoTime as described in the methods section using the system IRF (grey). For visualization, curves are averaged over 5 time-bin windows. Open probes were fit to a monoexponential decay. Closed probes were fit to a bi- or triexponential decay. For all curves, $\chi^{2}<2$.

* A_Cy3B/BHQ1 SLBs were prepared using $0.2 \mathrm{~mol} \%$ biotinyl-cap PE. All other SLBs were prepared with $0.1 \mathrm{~mol} \%$ biotinyl-cap PE. $\tau_{A v A m p}$ and $\tau_{A v \text { Int }}$ represent the mean $\pm$ s.e.m. of at least 3 experiments per condition. For $\tau_{A v F A S T}$, error reflects the histogram width, and s.e.m. is shown in parentheses. Here, QE represents the mean $\pm$ s.d. of at least 3 experiments per condition calculated using $\tau_{A v A m p}$.

Figure S9 Analysis of intensity and lifetime derived quenching efficiencies.

Scatter plots of quenching efficiencies calculated using the fluorescence intensity (I) versus the amplitude-average lifetime ( $\tau_{A v A m p}$ ). Bars and error bars represent the mean $\pm$ SD for at least 3 experiments. Outliers beyond 3 median absolution deviations were omitted. Statistics were performed using a two-tailed unpaired T-test. P values are reported as ns $\mathrm{P}>0.05, * \mathrm{P}<0.05, * * \mathrm{P}$ $<0.01, * * * \mathrm{P}<0.0001, * * * * \mathrm{P}<0.0001$.
A. $3^{\prime}-\mathrm{C} 3($ Biotin $)$

B. 5'-Dual Biotin

Figure S10 Structural analysis of biotin and streptavidin
(A) Chemical structure of 3' Biotin (Biosearch Technologies). (B) Chemical structure of 5'-Dual Biotin (Integrated DNA Technologies). The region in red was modeled in WebMO to determine its 3D end-to-end distance. (C) 3D model of the dual biotin linker. The yellow dashed line was used to measure the end-to-end distance. (D) 3D crystal structure of streptavidin with bound biotin molecules. The yellow dashed line was used to determine the distance between biotin-binding sites.

Figure S11 S_Cy3B/BHQ1- fluorescence lifetimes as a function of open probe density and probe biotinylation

Average $\tau_{A v \text { Int }}$ (dark blue) and $\tau_{A v A m p}$ (light teal) for SLBs containing S_Cy3B/BHQ1-probes anchored with a single or dual biotin. Data represent the mean $\pm$ s.e.m of 3 experiments. All SLBs containing closed probes displayed multiple lifetime components regardless of probe biotinylation.

Figure S12 Analysis map for podosome identification on high QE probes

The FLIM photon counts image was illumination profile corrected and used to select regions of interest containing a podosome-forming cell and the SLB background. Podosomes were detected by the presence of bright rings in the photon counts image. Scale bar, $5 \mu \mathrm{~m}$.

Figure S13 Analysis map for podosome identification on low QE probes

The FLIM photon counts image was illumination profile corrected and used to select regions of interest containing a podosome-forming cell and the SLB background. Podosomes were detected based on the decrease in fluorescence intensity at the podosome cores and rings were included through mask dilation. Scale bar, $5 \mu \mathrm{~m}$.

Figure S14 Analysis map for podosome identification on A_Cy3B/BHQ1- Linear probes

The FLIM photon counts image was illumination profile corrected and used to select regions of interest containing a podosome-forming cell and the SLB background. Individual podosome depletion regions were hand-selected and pixels were dilated to include the entire podosome region. Scale bar, $5 \mu \mathrm{~m}$.

Figure S15 Tension signal is primarily contributed by hairpin unfolding.
(A) Schematic of linear control probes, which lack a stem-loop sequence and cannot mechanically unfold. Probes may be transported on the SLB, leading to a change in intensity, but even under cellular forces, oligos cannot unfold. (B) Linear control probes mimicked tension probes but lacked a stem-loop sequence. Backbone spacer sequences were incorporated as indicated. (C)

Representative fluorescence micrographs of NIH 3T3 cells forming podosomes on SLBs with linear probes. Transmitted images are shown in the upper left of the corner of the Counts image. White boxes indicate zoom-in regions shown in the lower right corner. (D) Histogram analysis of the images shown above in C . For each probe, N random pixels were selected in the SLB background, where N was the number of pixels in the podosome region. (E) Quantification of the change in $\Delta \tau_{A v F A S T}$ on the 6 evaluated tension probes. Small teal markers represent data points from individual cells; large blue markers represent the mean per bioreplicate. Error bars represent the mean $\pm$ s.e.m. A two-tailed t-test was used to determine whether the mean was significantly different than zero. Experiments were repeated at least 3 times. Significance is as indicated, with ns, $\mathrm{P}>0.05,{ }^{*}, \mathrm{P}<0.05$, and ${ }^{* *}, \mathrm{P}<0.01$. Scale bar, $5 \mu \mathrm{~m}$.
